for

Improved System and Methods for Transportation and Delivery Using Bar Codes

SPECIFICATION

10

REFERENCE TO RELATED APPLICATIONS

Sub A1 ~~This application claims the benefit of provisional application of U.S. Serial No. 09/483,167, filed November 6, 2000.~~

BACKGROUND OF THE INVENTION

15

The present invention relates to an improved system for transportation and delivery using bar codes to uniquely identify customers and delivered goods in a secure and quick manner.

The Internet has produced a proliferation of e-commerce transactions. While e-commerce transactions offer convenience and speed to customers seeking to purchase goods online, most e-commerce transactions must end with the physical delivery of goods to a consumer. Indeed, the delivery stage is particularly prone to error or sabotage as goods may be inadvertently or maliciously routed to the wrong destination. The ability to secure the delivery of goods to the consumer in a manner that inspires confidence in both parties would be of great benefit to both providers of goods and the consumers who use them.

SUMMARY OF THE INVENTION

Therefore, the proposals of the related art fail to comprehensively overcome the problems discussed above and other related problems. Advantages of this invention will be set forth in part in the description which follows, and in part will be obvious from the description, or may be learned by practice of the invention. The advantages of the invention will be realized and attained by means of the elements and combinations particularly pointed out in the appended claims.

The present invention provides an improved method for the handling of packages and other e-commerce transactions using bar code technology and, in particular, the use of the security features available in two-dimensional bar codes, such as, for example, PDF-417, which was developed by Symbol Technologies, Inc., the assignee of the present invention. In further embodiments, the security of a transaction is assured by

using the ability of a two-dimensional bar code to reliably verify the identity of a participant in the transaction by comparing biometric data provided by the user in a one-time secure transaction (which is recorded within the two-dimensional bar code) and biometric data provided by the user of the system just prior to entering a transaction.

5 It is to be understood that both the foregoing general description and the following detailed description are exemplary and explanatory only and are not restrictive of the invention, as claimed.

BRIEF DESCRIPTION OF THE DRAWINGS

10 The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate embodiments of the invention and together with the description, serve to explain the principles of the invention.

Figure 1 illustrates a computer program capable of printing a check with a two-dimensional bar code.

15 Figure 2 illustrates a check incorporating a two-dimensional bar code that includes signature information printed using a computer program.

Figure 3 illustrates in flowchart form a method of practicing an embodiment of the present invention.

Figure 4 illustrates a sample receipt that may be used in practicing an embodiment of the present invention.

Figure 4A illustrates another form of a sample receipt that may be used in practicing an embodiment of the present invention.

5

DETAILED DESCRIPTION OF THE EMBODIMENTS

Reference will now be made in detail to the embodiments of the invention, examples of which are illustrated in the accompanying drawings.

The proper identification of a party in a proposed transaction of goods,
10 information or services may be ascertained by the use of a two-dimensional bar code. The need to encode more information in a smaller space has driven the development, standardization, and growing use of two-dimensional bar codes. Where traditional one-dimensional bar codes act as a pointer to reference information stored in a database, two-dimensional codes can function as the database itself, and therefore assure complete
15 portability for two-dimensional labeled items.

For example, PDF417, or Portable Data File 417, is a two-dimensional stacked bar code symbology capable of encoding over a kilobyte of data per label. The “portable data file” approach is well suited to applications where it is impractical to store item information in a database or where the database is not accessible when and where the
20 item’s bar code is read. In addition, PDF417 is an error-correcting symbology designed

for real-world applications where portions of labels can get destroyed in handling. It performs error correction by making calculations, if necessary, to reconstruct undecoded or corrupted portions of the symbol. A user may define one of 9 error correction levels labelled levels 0 to 8. All error correction levels, except Level 0, not only detect errors
5 but also can correct erroneously decoded or missing information.

PDF 417 also has the feature of Macro PDF417. This mechanism allows files of data to be represented logically and consecutively in a number of 'PDF417' symbols. Up to 99,999 different PDF417 symbols can be so linked or concatenated and be scanned in any sequence to enable the original data file to be correctly reconstructed. In particular,
10 PDF417 has been demonstrated to be effective in communicating large data files and to be easily scannable with existing proven hand-held technologies. Successful installations and broad supplier support further supported its selection. Detailed decision factors included:

- Demonstrated robust error correction
- 15 • Demonstrated to be readable with a wide range of scanner technologies including laser, linear CCD and imagers
- Demonstrated robust non-contact reading performance
- Best backward compatibility with the scanning of one-dimensional bar codes in existing applications.
- 20 • Proven track record and field performance

Based on the versatility of the two-dimensional bar code, it is possible to use the code as a key to access information. For example, a consumer desiring certain

information or goods from a provider presents a bar code previously obtained from the provider which encodes information about the consumer that only the consumer himself or herself can verify. If the provider matches the information from the bar code with the information presently provided characteristics of the user, the provider can allow access
5 to the desired information or goods without fear that a fraud or mistake has taken place.

For example, as illustrated in Fig. 1, a computer program is used to generate a request to print a check. The user inputs the requisite information including his or her signature using, for example, a pen tablet. The computer program then prints a check similar to the form in Fig. 2, which includes information about the user's signature and
10 other pertinent data encoded in the PDF 417 bar code on the check. The user then may sign the check in the normal fashion in the lower right hand corner. Upon receipt, the bank may verify the authenticity of the signature by scanning both the PDF 417 bar code and the signature and comparing them. If they are substantially identical, the authenticity is verified. This concept can be expanded to include any type of biometric data such as
15 facial appearance, signatures, thumbprints, handprints, voice prints and retinal scans and any type of transaction where a secure and inexpensive method of authentication is desired by each party.

In an embodiment of the present invention, a Mail Item Retrieval System (MIRS) may be utilized. There are 38,000 retail postal locations and an unlimited number of non-
20 USPS commercial sites where MIRS can be located. The MIRS provides customers with the freedom to pick up their package 24 hours a day, seven days a week. In a further embodiment, the MIRS may be located at a user's home or place of business.

The MIRS is based on the concept that each user need only provide select biometric data to the MIRS provider once in a secure fashion. At this time, the user also provides his or her location information which may include the user's address, phone numbers and e-mail contacts. The user may also provide financial information to the MIRS, such as a credit card number. This biometric data is then stored into the MIRS to be encoded into future two-dimensional bar codes provided to the user in electronic format and thereafter printed by the user on his or her personal printer. The MIRS may also provide security guarantees that creates a firewall between the biometric information.

Once an account is established with the MIRS, the user may directs that providers of goods send merchandise purchased over the phone or the Internet be sent to his or her mailbox account with the MIRS. Providers and other providers of goods and services may also interact with the MIRS provider.

Turning now to Figure 3, shown is a flowchart of using the MIRS, which is an embodiment of the present invention. In step 10, a user receives notification of a package's arrival at the MIRS facility. Such a notification could occur via voicemail, electronic mail, a cell phone, a pager or a PDA. The notification will include an attachment for printing an appropriate receipt. In step 20, the user at his or her convenience retrieves the information about the package received and in particular obtain a printed copy of a receipt including such information. The receipt will include a two-dimensional bar code, such as PDF which will incorporate information provided by the user to identify himself or herself previously to the system

The bar code on the receipt may contain biometric data that is a unique to the user and that has been previously provided in a secure manner to the entity providing the notification service. Such biometric data may include, for example, voice-print fingerprint, hand-print, retinal scan information, signature information, facial features or any other unique identifying features about the user. As shown in Figure 4, the printed receipt obtained may also include information necessary for the user to obtain the package. Such information may include the nature of the package, the dimensions of the package and the location where the package currently resides. The security of the MIRS is guaranteed by the fact that the receipt cannot be used to retrieve the package from the MIRS unless and until it is countersigned by the correct user. If anyone other than the correct user attempts to sign the receipt and retrieve the package, the MIRS will not release the package because the biometric signature information contained in the two-dimensional bar code and the signature will not match. This security technique may also be used for other biometric data.

Returning to Figure 3, in step 30, the user brings the printed receipt to of the location of the package, at this location the user then it provides the required biometric data to the package provider. For example, the user may affix his or her signature on the printed receipt just prior to arriving at the package retrieval facility. As shown in step 40, at the package retrieval facility which may be at a post office or other central location or even an the user's home, the user has the MIRS scan the two-dimensional bar code and also provides the necessary biometric data to the retrieval system. The act of providing such data may be accomplished by signing the receipt in the space indicated and having the MIRS scan the signature or by providing a retinal scan handprint, fingerprint or voice

print to the MIRS. Alternatively, the MIRS could use a camera to scan the facial features of the user and compare the biometric data retrieved from that scan with the biometric data retrieved from scanning the two-dimensional bar code.

In step 50, the MIRS compares the previously obtained biometric data encoded in
5 and the two-dimensional bar code with the currently obtained data biometric data provided by the user. If the two sets of data match, the retrieval system than provides the package to the user. As shown in step 60, the retrieval system may present the user with the package in order for the user to confirm that that is the actual package that is desired. In a further embodiment, the MIRS can arrange that the provider of the goods only
10 charge the user's credit card once the user has actually retrieved the package. This can be accomplished without having the MIRS reveal the user's financial information to the provider.

In a further embodiment, the MIRS may employ the signature-capture system using electro-optical scanning as disclosed in U.S. Patent No. 5,138,140, which is hereby
15 incorporated by reference in its entirety. Two-dimensional information such as a written signature can be captured and subsequently reconstructed by using an electro-optical scanner. A multi-row preamble code and a multi-row postamble code flank the signature, and each code has a row identifier for identifying which row is being scanned by a scan line emitted by the scanner, as well as start/stop data for identifying when each scan line
20 traverses the boundaries of a space containing the signature.

The occupied zones, i.e. those having parts of the signature, present a different light reflectivity to the scanner than the non-occupied zones, i.e. those having no parts of

the signature. The occupied zones are akin to bars, while the non-occupied zones are akin to spaces of a UPC symbol. The occupied zones represent binary ones, and the non-occupied zones represent binary zeros. When a scan line of the scanner traverses a row of zones in the space, the occupied zones reflect less light than the non-occupied zones, and this light-variable information can be processed into data representative of the signature in a manner completely analogous to that are known in the art for processing a UPC symbol.

However, unlike a UPC symbol, which is one-dimensional and can be scanned and read by a scan line anywhere along its height (i.e. the transverse "Y" axis), a signature is two-dimensional since it contains different information in both the longitudinal ("X" axis) and the transverse ("Y" axis) directions. To decode a two-dimensional signature, it is further necessary to know which row of zones is being scanned by a particular scan line and also when each scan line enters and exits the space containing the signature.

The signature scanner uses a multi-row preamble code means, and a multi-row postamble code means, respectively located forwardly and rearwardly of the space as considered along the longitudinal direction. Each code means is a multi-tiered symbol structure having electro-optically scannable and readable encoded data arranged along the longitudinal and transverse directions. Each symbol structure can be a unique two-dimensional marking symbol structure, a tiered bar code, or a new symbol structure compatible with prevailing standard bar code symbology. As shown in Figure 4A, each code means arranges its encoded data in a plurality of longitudinally-extending rows 1, 2,

3, 4 . . . N, where N is a substantially large enough number to provide adequate resolution of the signature. In theory, an infinite number of rows would provide the sharpest resolution, but, in practice, 25 rows are sufficient to provide an adequately resolved signature. The rows are tiered, i.e. stacked one above another, in the transverse direction.

- 5 Each row of encoded data also includes synchronizing means, i.e. start/stop data, for identifying when each scan line traverses the anterior and posterior boundary lines of the signature space.

- In a further embodiment, the scanning described above may be accomplished by the user using a device independent from the MIRS, such as, for example, a stand-alone
10 portable scanning device or a scanner integrated into a cell phone, PDA, or pager.

- The returns process is a large and looming problem for retailers, e-tailers, catalog companies and the USPS. The MIRS may be used in a similar manner for the return of packages to a provider. After notifying the provider of the goods that a return is desired, the provider can take the opportunity to ascertain why the user wishes to return the item.
15 Such notification may be done by phone or over the Internet. Once the provider is notified, the provider can use the MIRS to electronically deliver a return receipt to the user. The user may then print the receipt, which will include a two-dimensional bar code including encoded biometric information of the user. The receipt may also include information about addressing the package for a return including the location of the MIRS,
20 the address to which the package should be sent and postage return information. Such information may also be printed out as a separate mailing label, which may be affixed to the return package.

Similar to the acquisition process, the user brings the printed receipt to the MIRS. At this location the user then it provides the required biometric data to the MIRS. For example, the user may affix his or her signature on the printed receipt just prior to arriving at the package retrieval facility. At the package deposit facility which may be at
5 a post office or other central location or even an the user's home, the user scans the two-dimensional bar code and also provides the necessary biometric data to the retrieval system. The act of providing such data may be accomplished by signing the receipt in the space indicated and scanning the signature or by providing a retinal scan or handprint, fingerprint, voice print to the MIRS. Alternatively, the MIRS could use a camera to scan
10 the facial features of the user and compare the biometric data retrieved from that scan with the biometric data retrieved from scanning the two-dimensional bar code. The user may then deposit the package in the MIRS in a secure manner.

In a further embodiment, the MIRS could analyze the returned package physical characteristics such as its size and weight to make a determination whether the goods to
15 be returned are actually in the package. The MIRS would compare the measured physical characteristics of the package with those previously provided by the provider. If the analysis reveals that the actual package characteristics differ from the expected characteristics, the user at the MIRS could be given the opportunity to verify that the package actually contains the goods that are to be returned. If the analysis reveals that
20 the actual package characteristics match the expected characteristics, the MIRS could arrange for the provider to immediately refund the purchase price by crediting the credit card of the user if the user has chosen to provide this information to the MIRS. Such a
